Introduction:

Cerebral palsy is a non-progressive brain disorder that affects movement and coordination. It can also affect sensation, thinking, and communication. The condition occurs due to early brain injury during pregnancy, birth, or early childhood.

Problems Faced by CP Patients:

1. Motor Problems:

Children may have difficulty controlling muscles, leading to stiffness, weakness, or uncontrolled movements.

2. Communication Issues:

Many children cannot speak clearly or express their needs effectively.

3. Associated Conditions:

They may have epilepsy, vision/hearing problems, or learning difficulties

4. Daily Activity Limitations:

Difficulty in walking, eating, and performing basic activities independently.

5. Musculoskeletal Problems:

Issues like joint stiffness, posture problems, and spine deformities.

Existing Solution:

1. Medical Treatment:

Medicines and injections are used to reduce muscle stiffness.

2. Therapies:

- Physiotherapy improves movement

- Occupational therapy improves daily skills

- Speech therapy improves communication

3. Assistive Devices:

- Braces (orthoses)

- Communication boards

- Special equipment

4. Advanced Methods:

Robotic training and special exercises are used to improve mobility.

Limitations:

1. Early diagnosis is difficult.

2. Exact cause is often unknown.

3. Not all treatments are fully effective.

4. Some advanced treatments lack strong evidence.

5. Patients still face long-term communication and mobility challenges.
